Author bios:

Emir Efendić is a post doctoral scholar at the School of Business and Economics in Maastricht University in the Netherlands. His research focuses on judgment and decision-making.

Subramanya Prasad Chandrashekar recently completed a research assistant professor position with the Lee Shau Kee School of Business and Administration at the Hong Kong Metropolitan University. His research focuses on social status, lay-beliefs, and judgment and decision-making.

Cheong Shing Lee, Lok Yan Yeung, Min Ji Kim, Ching Yee Lee were students at the University of Hong Kong during the academic year 2019-20.

Gilad Feldman is an assistant professor with the University of Hong Kong psychology department. His research focuses on judgment and decision-making.

Declaration of Conflict of Interest:

The author(s) declared no potential conflicts of interests with respect to the authorship and/or publication of this article.

Financial disclosure/funding:

The research was supported by the Teaching Development Grant of the University of Hong Kong.

Subramanya Prasad Chandrashekar would like to thank Institute of International Business and Governance (IIBG), established with the substantial support of a grant from the Research Grants Council of the Hong Kong Special Administrative Region, China (UGC/IDS 16/17), for its support.

Authorship declaration

Gilad led the project, supervised each step of the project, conducted the pre-registration, and ran data collection. Emir and Prasad followed up on initial work by the other coauthors to verify and conduct additional analyses, and completed the manuscript draft. Emir, Prasad, and Gilad jointly finalized the manuscript for submission.

Cheong Shing Lee, Lok Yan Yeung, Min Ji Kim, and Ching Yee Lee conducted the replication and extension as part of university course work. They conducted an initial analysis of the paper, designed the replication, initiated the extensions, wrote the pre-registration, conducted initial data analysis, and wrote initial replication reports.

Abstract

Risks and benefits are negatively related in people's minds. Finucane et al. (2000) causally demonstrated that increasing risks of a hazard leads people to judge its benefits as lower. Vice versa, increasing benefits leads people to judge its risks as lower (original: r = -0.74[-0.92,-0.30]). This finding is consistent with an affective explanation and the negative relationship is often presented as evidence for an affect heuristic. In two well-powered studies, using a more stringent analytic strategy, we replicated the original finding. We observed a strong negative relationship between judgments of risks and benefits across three technologies, although we do find that there was no change in risks when highlighting low benefits. We note that risks seem to be more responsive to manipulation (as opposed to benefits) and find evidence that the negative relationship can depend on incidental mood. We provided materials, datasets, and analyses on https://osf.io/sufjn/.

Keywords: affect heuristic; judgment and decision making; heuristics; risk; replication

Risky therefore not beneficial: Replication and extension of Finucane et al. (2000)'s Affect Heuristic experiment

Introduction

People tend to view risks and benefits as negatively related: the riskier something is, the less beneficial it is. However, risks and benefits are distinct concepts and are sometimes even positively correlated – some technologies or hazards that are beneficial may be high or low in risk, but those that are not beneficial are unlikely to be high in risk. In a seminal paper, Finucane et al. (2000) proposed that the negative relationship occurs due to an *affect heuristic* (AH) whereby people rely on affect when judging the risks/benefits of specific hazards. Further, they demonstrated evidence that is consistent with an affective explanation of this relationship. Take nuclear energy for example. The AH proposes that increasing the risks of nuclear energy (e.g., by exalting the hazard uranium has for human health) turns the affective evaluation associated with it negative, thereby leading people to judge its benefits as lower. Vice versa, increasing benefits leads to positive affect and to people judging its risks as lower (see Table 1).

Table 1

Manipulated attribute	Impact on Affect	Impact on non-manipulated attribute
Risk is high	Negative affect	Benefit is low
Risk is low	Positive affect	Benefit is high
Benefit is high	Positive affect	Risk is low
Benefit is low	Negative affect	Risk is high

Summary of the predictions according to the Affect Heuristic (AH)

Affect Heuristic

Affect is a crucial component of people's decision-making (Kahneman, 2003; Kahneman, 2011; Lerner et al., 2015; Loewenstein et al., 2001; Rachlin, 2003). It is argued that reliance on affect is often a much quicker, easier, and more efficient way to navigate the complexities of everyday decision-making (Damasio, 1994; Schwarz & Clore, 1983) and that affect informs many judgments and decisions (Albarracín & Kumkale, 2003; Peters et al., 2006; Schwarz, 2012; Slovic et al., 2002; Wyer et al., 1999).

Early studies of risk perception have shown that feelings of dread are major determinants of public perception and acceptance of risk, for a wide range of hazards (Slovic, 1987). Focusing on this link, Finucane et al. (2000) proposed that people use an *affect heuristic* (AH) when making risk judgments. According to this view, people may use their affective response to a risk (e.g., "How do I feel about nuclear energy?") to infer how large they consider the risk to be. The argument being that: "Using an overall, readily available affective impression can be far easier – more efficient – than weighing the pros and cons or retrieving from memory many relevant examples, especially when the required judgment or decision is complex or mental resources are limited" (Finucane et al., 2000, p. 3).

Reliance on affect is a general process and, consistent with an AH, a wide range of findings supports the idea that affect provides valuable information that people use to simplify their decision-making. For instance, affect-laden imagery has been shown to predict people's preferences in investment decisions (MacGregor et al., 2000), smoking (Benthin et al., 1995), information integration (Anderson, 1981; Efendić et al., 2019), in simple choice gambles (Bateman et al., 2007), as well as morality judgments (Slovic & Västfjäll, 2010).

Risks and benefits

For a long time, the negative relationship between judgments of risks and benefits puzzled researchers (Fischhoff et al., 1978) as these judgments should be positively correlated or independent of one another (Slovic, 1987). In a breakthrough study, Alhakami and Slovic (1994) found that the negative relationship was linked to how a person generally feels about a hazard. Later, Finucane et al. (2000) showed that the inverse relationship between risk and benefits was strengthened under time pressure designed to limit analytic thinking (their Study 1) and that it is causally determined. Specifically, manipulating one attribute – e.g., increasing risk – led to an affectively congruent, but inverse relationship, i.e., decreased benefit and vice-versa (their Study 2).

This inverse relationship has been observed elsewhere as well. It has been found that when general negative affect is evoked (i.e., participants were shown photographs depicting houses in flooded regions), this led to increased levels of perceived risk (Keller et al., 2006). Similarly, incidental negative affect (e.g., negative mood) was found to amplify reliance on affect which led to stronger negative correlations between risks and benefits (Västfjäll et al., 2014). Interestingly, affective association with a particular hazard has been shown to influence the interpretation of new information. People evaluated nuclear power more negatively than solar power because of more negative feelings associated with nuclear power (Siegrist & Sütterlin, 2014). Similar negative associations between risk and benefits have been found in consumer judgments of novel products (King & Slovic, 2014), in the financial domain (Ganzach, 2000), and wood smoke pollution (Bhullar et al., 2014). Recently, Skagerlund et al. (2020) found that the negative correlation is tied to cognitive reflection ability.

Replication value and present research

In this paper, with two well-powered studies, we aimed to closely replicate and extend our understanding of the causal demonstration of the negative relationship between risks and benefits, using the same materials and procedure as in the original paper (Finucane et al., 2000).

We chose to replicate Study 2 from Finucane et al. (2000) for several reasons. First, while many correlational studies have found the negative relationship, few demonstrated it causally. King and Slovic (2014) used a similar method as Finucane and colleagues, but other work mostly found correlational support (some research has even failed to find the same relationship, Raue et al., 2019). There is therefore value in demonstrating, with sufficient statistical power, whether the causal effect is robust. Second, the analysis approach used in the original studies and in later demonstrations of the negative relationship (e.g., King & Slovic, 2014) were non-standard, failing to account for non-independence of data and relying on counting the number of times the manipulation worked in the predicted direction – a strategy that leads to large information loss. A more stringent analytic approach with mixed-effect modeling ought to provide information on the generalizability of the effect. Third, the findings are relevant for risk communication. Changing risk/benefit judgments by manipulating solely one attribute (either risk or benefit) has vast applied potential. Risk campaigns can focus on changing people's judgments about many plights of today's society (e.g., smoking, obesity, etc.). Fourth, as of this writing, we are unaware of any other attempts to directly replicate this study. This is surprising given the relevance in understanding the relationship between risks and benefits, as well as the popularity of the original paper and how it promoted the AH in the judgment and decision-making literature. As of this writing, the original paper has been cited 3363 times with a later updated review paper being cited 3860 times (Slovic et al., 2007).

We also wish to highlight an important distinction. The observation of the negative relationship is often presented as evidence for an AH in risk judgments. For example, observing the negative relationship leads authors to conclude that the AH is a robust phenomenon (Skagerlund et al., 2020). However, the original, as well as many other studies, fail to demonstrate that it is affect that mediates this relationship (although converging evidence on the importance of affect would suggest this is the case). Our aim here is to replicate the negative causal relationship between risks and benefits. As such, this replication also does not speak to the mechanism that underlies the relationship. Other more cognitive, rather than affective, mechanisms remain a plausible explanation. Nevertheless, we hope that investigating whether the causal relationship replicates will a) provide important insight into this interesting phenomenon, and b) serve other researchers who wish to use the paradigm to further understand whether it is affect, or something else that explains it.

We thus consider this investigation to be a needed direct replication. Replications should be sufficiently similar to the original study to adequately gauge support for the original findings (LeBel et al., 2019). Furthermore, given the prevalence of publication bias (Bakker et al., 2012), a close replication adds value by providing evidence that strengthens or weakens the finding.

Overview of studies

This replication was part of an ongoing replications project (see Figure S1 and the project process section in the supplementary for more details). We crowdsourced the replication using two teams, both teams being supervised by experienced authors. Each team collected data independently and wrote detailed pre-registrations. We thus report the results of two studies serving as close replications of Study 2 from Finucane et al. (2000), using the same methodology

and the same materials¹. The two studies differ only in the target sample, one obtained on MTurk (US participants), the other on Prolific (UK participants). The two studies were pre-registered on the OSF (MTurk: <u>https://osf.io/ab5dw/files/;</u> Prolific: <u>https://osf.io/p4qjx/files/</u>)². All materials, datasets, and analysis scripts are available on OSF (<u>https://osf.io/sufjn/</u>). We report how we determined the sample size, all data exclusions (if any), all manipulations, and all measures.

Extensions

In addition to the direct replication of Study 2 from Finucane et al. (2000), we also report two extensions. First, we looked at the effect of naturally occurring incidental mood on the negative relationship between judgments of risks and benefits. In the Mturk sample, participants were asked to rate their current levels of a) pleasure – *unpleasant* vs. *pleasant* and b) arousal – *deactivated* vs. *activated* (using two affective sliders that ranged from -100 to 100, centered in the middle). We based our measure on core affect which represents states experienced as simply feeling good or bad, energized or enervated (Russell, 2003). We use the term "naturally occurring incidental mood" to highlight that this is a measured, rather than manipulated variable and that the affect in question is incidental (i.e., unrelated to the judgment at hand). Any affect that arises due to changes in risk/benefit descriptions is integral (i.e., affect stemming from the judgment target at hand). Several predictions can be made on how naturally occurring incidental mood could impact the negative relationship: a) incidental mood is misattributed (Schwarz, 2012) to risk/benefit judgments impacting the strength of the negative correlations, b) incidental

¹ We would like to thank the original authors for providing the materials.

² Note that the preregistrations follow a registered report format. This means that a manuscript-like document was produced reporting simulated random data results. Please see also the Read-me document in the wiki page on the OSF preregistrations here: <u>https://osf.io/pg3ae/</u> for a detailed guide on where to find information on preregistered materials, design, and analysis plan.

affect has a specific effect in that negative incidental affect leads to high risk and low benefit, while positive incidental affect leads to low risk and high benefit, not impacting the strength of the negative correlations or c) it has a negation effect where, akin to mood regulation models for example (Andrade, 2005), being in a pleasurable naturally occurring mood may interfere with people's ability to effectively map a negative change in integral affect (e.g., by describing risks as high). Highlighting the interaction between such incidental and integral states can offer insights into the role of affect in the negative relationship.

Second, we explored whether there was a stronger negative relationship when risks, compared to when benefits are manipulated. Illuminating this boundary condition could provide insight into which of these two attributes people find more informative or important for their risk-judgments.

Method

Participants

In the first study a total of 806 participants from the USA were recruited through MTurk using the TurkPrime platform (Litman et al., 2017). In the second a total of 1008 participants from the UK were recruited through Prolific. To determine the number of participants needed, we conducted a power analysis planning to detect the weakest effect size reported in the original *that was also significant* (at p < .05). Therefore, given our resource constraints, we based our power analysis on having 95% power to detect a Cohen's $d_z = 0.30$. This resulted in a suggested sample size of 147 participants per condition, and a total of 588 across 4 between-subject conditions. Finally, we aimed for a higher sample size between 750 to 800 participants, as this would also ensure we were able to detect a smaller effect size (Cohen's d_z) of .20 at 80% power. A comparison of the target article sample and the replication samples is provided in Table S1 in the supplementary.

To obtain the final sample, we first excluded (30 from MTurk sample, 40 from Prolific sample) participants following our pre-registered exclusion criteria³. Because the studies were identical, we combined⁴ them for the final data analysis, resulting in 1552 participants (*Mturk* = 776; *Prolific* = 776; M_{Age} = 38.99, SD_{Age} = 12.30; 822 females, 727 males, 3 would rather not say).

Design, Procedure, and Measures

Both studies had a 2 (Between-subject factor – Direction: High vs. Low) x 2 (Betweensubject factor – Manipulated Attribute: Risk vs. Benefit) x 3 (Within-subject factor — Technology Scenario: Nuclear Power vs. Natural Gas vs. Food Preservative) mixed-subject design (see Table S3 and Table S4 in the supplementary for more details and full descriptions of the measures and direction/attribute information). Please note that the second study (Prolific) included an additional experimental condition which was excluded due to a methodological issue⁵.

Participants were first asked to answer questions regarding the perceived benefit and risk of all three technologies (Nuclear Power, Natural Gas, Food Preservatives) – the same ones used

¹ Indicating a low proficiency of English, self-report not being serious about filling in the survey, who guessed the hypothesis, have done the survey before, who failed to complete the survey, and those not from the US/UK. Please see Table S2 in the supplement for more detail.

⁴ We ran all the models below with study included as a fixed effect and we did not find any evidence that the results differed between studies. Please see tables S9, S13, S18, and S23 in the supplement.

⁵ The additional experimental condition presented participants both information on risk *and* benefit. This presentation made it impossible to test the negative relationship and we saw fit to exclude it. Some 192 of the 968 participants in the prolific sample were in the excluded condition. Responses from remaining 776 prolific participants was included in the final analysis. Please see also note 2 in Table S1 and Table S5 in supplement for more details.

in the original study. The presentation of the technologies was randomized. Participants were asked two questions, in random order, for each technology, namely: "In general, how risky [beneficial] do you consider the use of nuclear power / natural gas / food preservative?"⁶, answering on a 10-point scale from 1 (*not at all risky [beneficial]*) to 5 (*moderate risk [benefit]*) to 10 (*very risky [beneficial]*).

Subsequently, dependent on the conditions, participants were presented with textual vignettes designed to change the affective quality (e.g., high risk = negative, high benefit = positive, etc.) of the scenarios. We used the same descriptions from the original study (<u>https://osf.io/y97tp/</u>). For example, in the low benefit condition for the hazard natural gas, participants were presented with the following text (shortened):

Natural gas is used as a source of energy in the US. Natural gas has the property of being a gas at room temperature, which allows it to be burned to produce heat. However, this same gaseous property limits the energy tasks that natural gas can be used for. Natural gas is not able to replace electricity for such tasks as lighting, or the numerous jobs that need electric motors, such as refrigeration or the operation of machinery.

After reading the information, participants again provided answers to the risk and benefit questions for each technology scenario. Please note that once participants were assigned to one of the between-subject conditions, they were in that condition for all three scenarios, as scenario was a within-subject variable. This means that we had data from 4656 trials. Finally, participants answered a funneling section and provided demographic information. At the end of the study, a short debriefing was given regarding the study's purpose and confidentiality. We characterize the current replication as a "very close replication" based on the framework for classification of the

⁶ In the original study, the question added the phrasing "...to U.S. society as a whole" at the end. We used this exact phrasing in the MTurk sample (which included people from the US) but decided to exclude this for the Prolific sample as these participants were from the UK.

replications using the criteria by LeBel et al. (2018) (see Table S45 in the supplementary material).

Results

Analysis strategy

We report both the original (i.e., repeating the same analytic strategy as in Finucane et al., 2000), as well as an improved analytic approach. For the improved, we employed linear mixedeffects models (LMEM) using the lme4 package in R (Bates et al., 2015). Significance for fixed effects was assessed via Satterthwaite's degrees of freedom (Kuznetsova et al., 2017). Unless stated otherwise, the models adjusted for covariates at Level 1 (ratings of risks and benefits before the experimental treatment) and Level 2 (i.e., Technology type and participants' ID were treated as random effects). We added pre-scores on the manipulated/non-manipulated attribute to reduce noise of our assessment and to check whether the pre-ratings may moderate the effect of the manipulation. LMEMs reduce the chance of Type I errors, account for non-independence of data points (e.g., within-subject observations), provide a greater flexibility with specification of the covariance structure, and allow us to make more generalizable claims across samples of participants and stimuli (hazards in our case) (Judd et al., 2012).

Original data analytic approach (Finucane et al., 2000)

Descriptive statistics of the measures across the two samples are noted in Table S39 and Table S40 of the supplementary material. Following the original approach, we conducted paired samples t-tests (two-tailed). Specifically, for each technology, we compared the mean pre- and post-manipulation ratings of the manipulated and the non-manipulated attributes. Positive tvalues indicate that there was an increase in rating after manipulation. Negative t-values indicate there was a decrease in rating after manipulation. The results are in line with the original finding (See Table S41- S44 in the supplementary material for the detailed results). That is, for the manipulated attribute ratings, providing information on high and low benefits or risks, led to higher and lower post-manipulation ratings of benefits or risks. For the non-manipulated attribute, we see the inverse: providing information on high and low benefits or risks led to lower and higher post-manipulation ratings of risk and benefits.

Further, we tested the correlation between risk and benefits using the *t* values from the above analysis. We found strong support for a negative correlation: MTurk sample: r(10) = -0.87, 95% CI [-0.96, -0.59], p = .003; Prolific sample: r(10) = -0.84, 95% CI [-0.95, -0.50], p < .001. Plotting the *t* values in Figure 1., the negative slope shows that when ratings on the manipulated attribute increase, ratings on the non-manipulated attribute decrease (and vice-versa). Simply put, when benefits increase risks decrease and when risks increase benefits decrease, indicating a negative relationship.

Figure 1. T-values for manipulated versus non-manipulated attributes

Note. t-values for four direction/attribute information manipulations (HB = High Benefit; LB = Low Benefit, HR = High Risk, LR = Low Risk) for the three technologies (nuclear power, natural gas, and food preservatives) across the two samples (MTurk and Prolific). The negative slope shows the predicted negative relationship between risks and benefits – as benefits increase risks decrease and as risks increase benefits decrease.

Mixed-model approach

Manipulation checks

We conducted LMEMs with change in the manipulated attribute as the DV (i.e., ratings on manipulated attribute after experimental treatment minus ratings on manipulated attribute before experimental treatment; 0 therefore indicates no change, a positive value an increase, while negative value indicates a decrease). Table 2 presents the fixed-effects coefficients with all the predictors (See Table S11–S14 in the supplementary material for step-by-step regression results).

DV: Change in manipulated attribute						
Predictors	B	<i>S.E</i> .	CI	р		
(Intercept)	-0.09	0.06	-0.21 - 0.04	0.185		
Pre-rating manipulated attribute (PMA)	-1.09	0.03	-1.151.03	<0.001		
Direction (High vs. Low)	2.56	0.07	2.42 - 2.69	<0.001		
Manipulated Attribute (Risk vs. Benefit)	-0.27	0.07	-0.400.13	<0.001		
Direction × Manipulated Attribute	0.49	0.14	0.22 - 0.75	<0.001		
PMA ×Direction	-0.10	0.06	-0.22 - 0.02	0.109		
PMA × Manipulated Attribute	0.01	0.06	-0.11 - 0.14	0.819		
$PMA \times Direction \times Manipulated$ Attribute	0.16	0.12	-0.08 - 0.40	0.199		

Table 2. Estimated fixed-effects coefficients of the mixed-effects regression model with change in the manipulated attribute as the DV.

Note: Variables were coded as follows—Direction: -0.5 = Low, +0.5 = High; Attribute: -0.5 = Benefit, +0.5 = Risk.

The significant effect of Direction shows that, regardless of the manipulated attribute, if the direction was high there was a positive change while if the direction was low there was a negative change, indicating a successful manipulation check (see Figure 2 and Tables S41- S44 for detailed statistics).

Figure 2. Distribution of ratings on change in manipulated attribute as DV by experimental conditions.

Note. Figure includes violin plot displaying distribution of responses, boxplot displaying the median, first, and third quartiles, while the mean value is identified by the red circle.

Negative relationship between risks and benefits

To test whether we observe a negative relationship between risks and benefits, we looked at the effects of the manipulated attribute on the non-manipulated attribute. Specifically, we regressed change in ratings of non-manipulated attributes (DV) on Direction, Manipulated Attribute, and their interaction, adjusting for covariates at Level 1 (Pre-rating manipulated attribute; and three-way interaction between pre-rating non-manipulated attribute, Direction, and Manipulated Attribute) and Level 2 (i.e., Technology type and participant's ID). Table 3 summarize these results (See Table S20-S24 in the supplementary material for step-by-step

regression results and model comparisons).

Table 3. Estimated fixed-effects coefficients of the mixed-effects regression model with change in the non-manipulated attribute as the DV.

DV: Change in non-manipulated attribute					
Predictors	В	<i>S.E</i> .	СІ	р	
Intercept	-0.26	0.10	-0.450.06	0.009	
Pre-rating manipulated attribute (PMA)	-0.21	0.03	-0.270.15	<0.001	
Pre-rating non-manipulated attribute (PNMA)	-0.95	0.03	-1.010.89	<0.001	
Direction (High vs. Low)	-1.15	0.06	-1.271.03	<0.001	
Attribute (Risk vs. Benefit)	0.55	0.06	0.43 - 0.67	<0.001	
PNMA \times Direction	0.14	0.05	0.04 - 0.25	0.008	
PNMA × Attribute	-0.16	0.06	-0.270.05	0.004	
Direction × Attribute	-1.34	0.12	-1.581.10	<0.001	
PNMA × Direction× Attribute	0.13	0.11	-0.08 - 0.35	0.221	

Note: Variables were coded as follows—Direction: -0.5 = Low, +0.5 = High; Attribute: -0.5 = Benefit, +0.5 = Risk.

The main effect of direction supports the original finding of the negative relationship. In addition, we find that the directionality of pre- and post-treatment changes in the non-manipulated attribute was consistent with the predicted inverse relationship, except in the Low-benefit condition (see Figure 3 and Tables S41- S44 for detailed statistics).

Figure 3. Distribution of rating on change in non-manipulated attribute as DV by experimental conditions.

Note. Figure includes violin plot displaying the distribution of responses, boxplot displaying the median, first, and third quartiles, while the mean value is identified by the red circle.

Exploratory analysis: Mediation effects

We also tested whether the effect of the experimental manipulation on change in the nonmanipulated attributes was mediated by the changes in the manipulated attribute as the analytic reasoning would suggest. To do this, we conducted a multilevel mediation analysis (this analysis was not part of the pre-registration). Bayesian estimation of the multilevel mediation model was performed using the *bmlm* R package (Vuorre & Bolger, 2018). Because our experimental design involved two directions (High vs. Low), we conducted two independent mediation analysis that looked at the responses within High and Low separately. Indeed, both sets of mediation analysis show a significant indirect effect of manipulation on non-manipulated attribute rating through manipulated attribute rating (High only mediation: $M_{posterior} = -0.54$, SD = 0.04, CI = [-0.61, -0.47]; Low only mediation: $M_{posterior} = 0.55$, SD = 0.04, CI = [0.48, 0.62]). For details results see Table S25 – S26 in the supplement.

Extensions

Naturally occurring incidental mood and the negative relationship between risks and benefits.

We conducted an analysis where the change in ratings of manipulated attributes, level of pleasure, level of arousal, and their interaction were set as predictors of change in the ratings of the non-manipulated attributes. Table 4 and Figure 4 summarize the results. As a representation of the negative relationship between risks and benefits, we looked at predicting change in non-manipulated attribute with change in manipulated attribute. Indeed, a negative correlation between these two variables represents the negative relationship. We decided to use this (rather than an interaction between the dummy coded direction and manipulated attribute) as it is easier to represent and interpret a potential two-way interaction with pleasure or arousal.

	DV: Change in non-manipulated attribute			
Predictors	В	<i>S.E</i> .	CI	р
(Intercept)	-0.59	0.15	-0.880.29	<0.001
Pre-rating non-manipulated attribute (PNMA)	-0.63	0.05	-0.720.54	<0.001
Pre-rating manipulated attribute (PMA)	-1.05	0.04	-1.130.97	<0.001
Pleasure	0.03	0.05	-0.07 - 0.13	0.557

Table 4. Estimated fixed-effects coefficients from the mixed-effects regression model adding pleasure and arousal measures on change in non-manipulated attribute as DV.

Pleasure
$$\times$$
 Arousal \times CMA-0.030.03-0.09 - 0.020.201We found some support that the negative relationship is moderated by incidental pleasure(see Figure 4). Specifically, the negative relationship was stronger among participants whoreported higher incidental pleasure in comparison to participants who reported lower incidentalpleasure.

Figure 4. The interaction between change in manipulated attribute and pleasure on change in non-manipulated attribute.

Risk/benefit strength.

We also examined whether there was a stronger negative relationship when risks, as opposed to benefits were manipulated and the extent to which it may depend on the manipulated conditions. For the analysis, similar to above, we again used the change in ratings of manipulated attributes, Manipulated Attribute (Risk vs. Benefit), Direction, and their interaction as predictors of change in the ratings of the non-manipulated attributes. Table 5 and Figure 5 summarize the results.

	DV: Change in non-manipulated attribute			
Predictors	В	<i>S.E</i> .	CI	р
(Intercept)	-0.24	0.13	-0.49 - 0.02	0.066
Pre-rating manipulated attribute (PMA)	-0.59	0.03	-0.650.53	<0.001
Pre-rating non-manipulated attribute (PNMA)	-1.01	0.03	-1.060.95	<0.001
Direction (High vs. Low)	-0.37	0.06	-0.490.24	<0.001
Manipulated Attribute (Risk vs. Benefit)	0.44	0.06	0.31 - 0.56	<0.001
Change in manipulated attribute (CMA)	-0.74	0.03	-0.800.68	<0.001
Direction × Manipulated Attribute	-0.85	0.12	-1.090.60	<0.001
Direction \times CMA	-0.12	0.05	-0.230.02	0.022
CMA × Manipulated Attribute	-0.27	0.05	-0.370.16	<0.001
Direction \times Manipulated Attribute \times CMA	0.22	0.11	0.01 - 0.43	0.037

Table 5. Estimated fixed-effects coefficients from the mixed-effects regression model looking at moderation of the negative relationship by risks/benefits.

Note: Variables were coded as follows—Direction: -0.5 = Low, +0.5 = High; Attribute: -0.5 = Benefit, +0.5 = Risk.

The interaction between manipulated attribute and CMA (change in manipulated attribute) indicates that the strength of the negative relationship between the manipulated and non-manipulated attribute was stronger when risks, as opposed to benefits were manipulated. Further, the three-way interaction (Direction × Manipulated Attribute × CMA) suggest that the extent of difference between risks and benefits varies as a function of direction of manipulation (High vs. Low). Proceeding to conducted separate analyses for Low and High conditions, results within the high condition show no support for an interaction. However, results within the low condition do find support for the interaction (See Table S32 and Table S33 in the supplementary material for detailed results). This lack of consistency leads us to conclude that the strength of the negative relationship between the manipulated and non-manipulated attribute being stronger when risks, as opposed to benefits were manipulated is mainly driven by participants' responses

within the Low-Benefit condition (see Figure 5). Specifically, we note large differences in change in ratings of non-manipulated attribute across Risk ($M_{change} = 0.74$ (SE = 0.05)) and Benefit ($M_{change} = -0.14$ (0.05)) manipulation within the low condition. However, those differences are much smaller within the high condition (Risk: $M_{change} = -1.01$ (0.06); Benefit: $M_{change} = -0.62$ (0.05)).

Figure 5. Relationship between manipulated and non-manipulated attributes as a function of risk/benefit manipulations.

General discussion

In two studies, using samples from the US and the UK, we re-did Study 2 from Finucane et al. (2000). With high power and using a more precise analytic approach, we successfully replicated and obtained a similar effect as in the original study providing support for the demonstration of a causal negative relationship between risks and benefit judgments. Specifically, we showed that increasing the risks of three technologies (nuclear energy, food preservatives, and natural gas), led to lower judgments on benefits while increasing the benefits led to lower judgments on risks. Vice versa, decreasing risks led to higher judgments of benefits. However, we did not find any differences in the low-benefit conditions. Specifically, decreasing the benefits did not lead to higher judgments of risks (See Table S41- S44 in the supplementary material for detailed results). In addition, we report two extensions. First, we found that the negative relationship between risks and benefits was stronger among participants who reported feeling higher incidental pleasure. Concurrently, people who felt pleasant may have generally relied more on heuristic processing – in the case the AH (Bohner et al., 1995). Previous findings, that manipulated negative mood, showed increased risk perceptions (Västfjäll et al., 2014). This may indicate that negative mood has a more pointed effect on risk-benefit judgments, although our findings cannot speak on this as we did not have a lot of data on the negative side of our measures, meaning we had few participants feeling low pleasure and low arousal (see Figure S5 in the supplement). This may have reduced our chances of obtaining more precise findings on how incidental affect can modulate the negative relationship. Further, it is important to note that we measured naturally occurring incidental mood whereas previous research manipulated the mood directly.

Second, we looked at whether manipulating risks or manipulating benefits impacts the strength of the negative relationship. Initially, our results showed the strength of the negative relationship was stronger when risks, as opposed to benefits were manipulated. However, a more detailed look shows that this effect is most likely a product of the fact that there was no impact on the non-manipulated attribute in the low-benefit condition (See Table S41- S44; the original findings seem to show this as well; See Table S34 and Table S35 in the supplementary material for detailed results). It is worth pointing out that manipulating low benefits did lead to a predicted change in benefits – people judged them as considerably lower (i.e., there was a successful manipulation; See Table S41- S44). But decreasing benefits did not lead to the predicted impact on risks. This may hint at the fact that providing low benefit info is not enough to lead to perceptible changes in affect as it may be that risks are simply better at evoking an

affective reaction (cf., Pachur et al., 2014). Our results also hint at the fact that people may pay more attention to risks—both increase and decrease in risks – while this is not the case for benefits, where only increase in benefits led to perceivable changes. Alternatively, the lack of impact on the non-manipulated attribute in the low-benefit condition may hint at sensitivity to the actual relationship of risks and benefits in the world, namely that they are often positively correlated. As mentioned in the introduction, technologies low in benefit are unlikely to be high in risk. It is of course not incommensurable that this sensitivity exists along a strong affective process that leads to negative relationships between risks and benefits.

Current findings may have important implications for risk communication (Thaler & Sunstein, 2008; Yang et al., 2014). For instance, communication efforts about new technologies ought to contend that risk information may overweigh other benefit information and is more malleable to manipulate. While out of scope for this research, it may be worth taking a closer look at what associations people might have with the terms "risky" and "beneficial". Specifically, people may already associate and interpret these terms as "bad" (for risky) and good (for beneficial), explaining the negative correlation.

We believe this replication strengthens the claim that it is possible to causally affect risk and benefit judgments. The negative relationship has been presented as a demonstration of the AH. However, while the effect is *consistent* with an AH, we (as the original finding) do not provide direct evidence that affect does mediate this negative relationship. Indeed, the negative relationship could also occur due to a more cognitive explanation. While we show evidence that change in manipulated attribute is a mediator between the manipulations and non-manipulated attribute, this may be one of potential mediators and the underlying cause remains uncovered. Some recent research has, for example, found more support for manipulations of availability by recall, rather than affect, to have a stronger impact on how risk judgments are constructed (Efendić, *in press*). Nevertheless, with this replication, we hope to encourage future researchers that this paradigm is robust and could potentially be used to tease apart any cognitive/affective explanations of risk/benefit judgments.

Finally, in our replication we focused on the original three technological scenarios as the risky hazards. While one could argue that people's attitudes towards these risks have changed in the intervening 20 years since the original study, impacting the strength of the negative relationship, our results indicate similar effects. This could indicate that either the attitudes did not change, or, equally likely, that the manipulations of risk/benefit go well and beyond beliefs and attitudes. In that sense, future work should look at whether the negative relationship extends to other hazards. For instance, Skagerlund et al. (2019) found that the inverse relationship extends to numerous other hazards, activities, and technologies.

Disclosures

Data collection

Data collection was completed before analyzing the data.

Conditions reporting

We report all the conditions we collected.

Variables reporting

All variables collected for this study are reported and included in the provided data.
Exclusion criteria for the two replication studies

- 1. Subjects indicating a low proficiency of English (self-report < 5, on a 1-7 scale);
- Subjects who self-report not being serious about filling in the survey (self-report < 4, on a 1-5 scale);
- 3. Subjects who correctly guessed the hypothesis of this study in the funnelling section;
- 4. Have seen or done the survey before;
- 5. Subjects who failed to complete the survey. (duration = 0, leave question blank);
- 6. Not from the United States/UK;

Project Process Outline

The current replication is part of the mass pre-registered replication project, with the aim of revisiting well-known research findings in the area of judgment and decision making (JDM) and examining the reproducibility and replicability of these findings.

The current replication followed the same project outline as noted below. For each of the replication projects, researchers completed full pre-registrations, data analysis, and APA style submission-ready reports. The authors independently reproduced the materials and designed the replication experiment, with a separate pre-registration document. The researchers then peer-reviewed one another to try and arrive at the best possible design. Then, the lead and corresponding authors reviewed the integrated work and the last corresponding author made final adjustments and conducted the pre-registration and data collection.

The OSF page of the project contains one Qualtrics survey design used for data collection with pre-registration documents submitted by each of the researchers. In the manuscript, we followed the most conservative of the pre-registrations.

Verification of Analyses

Initial analyses were conducted by the independent researchers, who used JAMOVI (jamovi project, 2018) or R for data analyses. In preparing this manuscript, the lead and corresponding authors verified the analyses in R.

Table S1. Sample differences and similarities between original study and our replications

¹We note the final sample size after exclusions.

² Please note that the Prolific sample included an extra between-subject condition that was aimed as an extension. However, we did not include this condition in the analysis as we found it difficult to draw conclusions from the results. We initially intended this extension to serve as a mixed condition, showing both risks and benefit information. However, we found it difficult to draw any reliable conclusions from this condition. Given that this condition was not pertinent, upon review, we decided not to include this exploratory extension condition in our reporting, though it is included in our shared data and code for those interested in further analyses. Thus, the 192 participants assigned to this condition were excluded leaving us with total of 776 participants in the Prolific sample as well. The equal number of participants between the two samples is purely due to chance. Please refer to Table S5 for a description of what participants read in the extension condition.

³Manucript was published during the year 2000, but the data collection time is unspecified in the original article.

Power analyses

Using G*Power (Fual et al., 2007), we conducted a power analysis to determine the sample size necessary to replicate the results described in Study 2 of Finucane et al. (2000). We based the power analysis on the t-values of each individual condition (affective information) – see "Original article's results" section reported below in this document. Given our resource constraints, we wanted to at least ensure we were able to detect the weakest effect size reported in the original study *that was also significant* (at p < .05). See Table S2 below. Finally, we aimed for a higher sample size between 750 to 800 participants, as this would also ensure we were able to detect a smaller effect size (Cohen's d_7) of .20 at .80 power.

Final Judgment: <u>After reading</u> the designated affective information of Nuclear Power					
(4 questions) ²					
Final Judgment: <u>After reading</u> the designated affective information of Natural Gas (4 questions) ²					
Final Judgment: <u>After reading</u> the designated affective information of Food Preservatives (4 questions) ²					

¹ The order of presentation of the technologies was not specified in the original experiment. The presentation was randomized in our replication studies.

² See Table S4 for the full description of the questions.

Participants were randomly assigned to one of the four affective information conditions. Before reading the affective information, participants were asked to provide their initial judgment on nuclear power, natural gas, and food preservatives. For each technology, they were asked to answer a set of 4 questions regarding perceived risk and benefit (see Table S4).

After that, dependent on the affective information condition, they read the affective information about each technology and provided the final judgment by answering the same set of questions as in their initial judgment. The order of presenting the evaluation questions

and vignettes was not specified in the original paper but was randomized in our replication studies. We conducted an additional analysis to check for any order effects (i.e., did the presentation order of technology scenario influence ratings for both non-manipulated and manipulated attributes). We do not find any support for order effects.

Dependent variables

1. Initial Judgment: Prior to the presentation of the affective information

Before the participants received the affective information of the technologies (nuclear power, natural gas, and food preservatives) from the experimenter, they were asked to evaluate these technologies regarding their perceived risk and benefit (4 questions for each technology scenario) on a 10-point scale.

The example given in the original paper on the natural gas condition was "In general, how beneficial do you consider the use of natural gas to be to US society as a whole?". Participants were asked to answer the question on a 10-point scale from "not at all beneficial" to "very beneficial" We used the same wording and scale in the MTurk sample (which had participants from the US) while the later part of the question ("to US society as a whole") was not included in the Prolific sample (which had participants form the UK).

Table S4.	Questions	used in the	he Original	Experiment
-----------	-----------	-------------	-------------	------------

Order ¹	Judgment question on perceived risk and benefit — 10-point scale
1	In general, how beneficial do you consider the use of <u>nuclear power</u> ² to be to U.S. society as a whole?
	From 1 "not at all beneficial" to 5 "moderate benefit" to 10 "very beneficial"
2	In general, how risky do you consider the use of <u>nuclear power</u> ² to be to U.S. society as a whole?
	From 1 "not at all risky" to 5 "moderate risk" to 10 "very risky"
3 ³	How likely do you think it is that there will be a major accident or problem (and consequently serious harm to people) within the next 5 years as a result of using <u>nuclear power</u> ² ?
	From 1 "very unlikely" to 10 "very likely"
4 ³	To what extent can the risks of using <u>nuclear power</u> ² be controlled by those who are exposed to those risks?
	From 1 "very little control" to 10 "very much control"

¹ The order of the first two questions was believed to be randomized and presented evenly. ² The factor underlined above was substituted to "natural gas" and "food preservatives" depending on the condition

2. Final Judgment: After Reading the Affective Information

The questions used in the final judgment were identical to the questions in the initial judgment. The participants were again asked to judge the perceived risk and benefit of each technology. The order of presenting the judgment questions was not specified in the original but was randomized in our replication studies. By making reference to the original experimental material, we believe that the order of Question 3 and 4 was fixed, while the order of Question 1 and 2 was dependent on the condition. In risk conditions, Question 2 (risk judgment) was presented first; in the benefit conditions, Question 1 (benefit judgment) was presented first.

³ Questions 3 and 4 were asked in the original paper, but it appears as they were not of relevance for the hypothesis so they were not reported.

Risk / Benefit descriptions, i.e., the affective information

See OSF for the original paper questionnaire used and the affective information presented to the participants across the conditions. We used the same descriptions as in the original article.

Comprehension checks

No comprehension check was mentioned in the original paper. Therefore, we decided not include comprehension checks in the replication studies.

Data gathering

There are variations in the physical settings. In the original study, the participants had to fill in a paper questionnaire under the supervision of the experimenters; in the current replication, the participants responded to a Qualtrics survey online, using their own electronic devices.

Extension scenario related to prolific sample

Participants in the Prolific sample assigned to Extension condition first reported the initial risks and benefits ratings on three technologies and proceeded to read descriptions about each technology (see table below) that contained information about both risks *and* benefits. After reading the vignette content, participants again provided answers to the risk and benefit questions for each technology scenario.

Affective Informati on	Technology	Vignette content
Extension condition	Nuclear Power	Nuclear power has a good safety record and an accident rate that is comparable with other industries that produce electricity. Part of the reason that risks have been low in the nuclear power industry is that the industry is heavily monitored and regulated by the federal government. All nuclear power plants have on-site federal regulators. The plants are also built to resist accidents. Even the most serious nuclear accident in United States history, Three Mile Island, did not harm anyone's health. On the other hand, nuclear power today produces only a small percentage of our nation's electricity. New methods of generating electricity, such as geothermal, solar power, and wind turbines, could eventually replace nuclear power. In addition, the application of energy-conservation methods could save more energy than is produced by nuclear power. Finally, the addition of electrical generators to the boilers of factories all over the United States could produce more power than is supplied by nuclear power, without the construction of any more plants of any sort.
	Natural Gas	Natural gas is one of the safest forms of energy. Accidents involving natural gas have been very rare. Modern gas pipelines and transportation networks have been constructed to high standards and are regulated by both state and federal government agencies. Today's appliances that use natural gas have been constructed to reduce the chance of accidents, with formerly dangerous items, such as pilot lights, replaced by electronic ignition of the gas. In addition, natural gas detectors are now available to warn consumers of any potential danger and home accidents are now almost unheard of. Natural gas was once almost free, since it was frequently discovered as a by-product during the drilling of oil wells. Today this is no longer true and natural gas costs ever increasing amounts of money to discover, develop and transport.
		It is possible to transport natural gas through the use of pipelines and liquefaction. However, compared to the ease with which other forms of energy, especially electricity, can be transported, the transportation of natural gas is not efficient.
	Food Preservatives	Food preservatives are chemicals added to food. The risks of food preservatives are much less than the risks from traditional methods of preservation, such as smoking or salting, which have been shown to cause such severe health effects as hypertension and cancer. In addition, the risk from food preservatives is very small when compared to the risk of eating

Table S5. Scenario descriptions of the removed experimental condition in the Prolific sample

	food that has started to spoil. The question today is: Are they still necessary? In most parts of the country rapid transportation, refrigeration, freezing, and the availability of locally produced food products makes it possible to get foods to market and to people's homes without using any preservatives at all.
	The amount of a preservative used in food is far too small to be a danger to people. Before a food preservative can be used in the United States it must pass years of tests to make sure that it will not cause illness in consumers.
	Although food preservatives have played an important role in the past, it appears that the need to use preservatives is declining today.

Additional results based on new data-analysis strategy

Original article's results

We reproduced the results of the original study to help us accurately pinpoint the effect sizes for our own replication and to verify the degree of reproducibility.

Sample size before and after exclusions

The original study did mention exclusion criteria, but we did note a discrepancy related to the number of participants that was left unexplained in the original paper. The original study method stated that 213 undergraduate students were recruited in the experiment; whereas, data analysis section stated that there were 219 participants in the experiment. Therefore, this replication study took the numbers from the data analysed (219 participants) to ensure the integrity of the subsequent analysis.

T-tests

In the original experiment, the authors conducted paired-sample t-tests to compare the mean difference of perceived benefit and risk ratings before and after reading the affective information. However, the original authors only reported the results for the *Low Risk* - *Nuclear Power* condition with the exact number. Nevertheless, the results for all the conditions were presented on a plot in the original paper (Exhibit 6 in the original paper). Therefore, we decided to infer the t-values from the plot using an online tool called WebPlotDigitizer: <u>https://automeris.io/WebPlotDigitizer/index.html</u> for the estimated t-values. See Table S34 and S35, for the t-statistics and Cohen's d_z (with 95% CIs) of the manipulated and non-manipulated attributes, respectively. These statistics were used in our power analysis.

		Manipulated Attribute			
Condition		t-statistics	Cohen's d _z with 95% CIs		
High Benefit ¹	Nuclear Power	<i>t</i> (55) = 1.74, p=.087	0.23[-0.03, 0.50]

¹ In the high and low benefit conditions, the manipulated attribute was benefit and the nonmanipulated attribute was risk

 2 In the high and low risk conditions, the manipulated attribute was risk and the non-manipulated attribute was benefit

³ The direction of change was not in line with the hypothesis

* The result was significant

Additional Analysis Mirroring original study results

Replication

Descriptive statistics of the measures across the two studies are noted in Table S39 and Table S40 of the supplementary material. To verify the effect of the manipulated attribute on the non-manipulated attribute, following the original experiment, we conducted paired samples *t*-tests (two-tailed). We contrasted people's judgments of risks and benefits for each particular technology before and after the implementation of the affective information (See Table S41–S44 in the supplementary material for detailed statistics). The findings show that, across both the MTurk and Prolific samples, the affective information did influence participants' judgments on perceived risks and benefits in the direction predicted by the AH. Specifically, this meant that increasing risks of a technology led to judgments of lower benefits of a technology led to judgments of lower soft at technology led to judgments of higher benefits. Vice versa, increasing benefits of a technology led to judgments of higher risks.

Similar to the original study, we then looked at the percentage of times the manipulation worked across both studies, i.e., when there was a directional change in the *manipulated* attribute which was consistent with the affective information (e.g., judgments of perceived risk decreased after receipt of information saying risk was low, etc.). As indicated in Table 36, in the MTurk sample, overall the manipulation worked in 53.2% of trials. The manipulation worked to a greater degree (63.1%) in the Prolific sample. Our results are similar to those obtained in the original experiment (there, the manipulation worked in 50% of the trials).

Table S36

Effect of the affective manipulation on the attribute that was manipulated across both studies, overall, and dependent on condition.

Study	Condition	Percent of trials that manipulation worked	Percent of trials that effect was opposite manipulation	Percent of trials no change
	High benefit	42.2	15.0	42.9
	Low benefit	53.1	15.0	31.9
Study 1	High risk	56.3	12.2	31.5
(Mturk	Low risk	61.3	12.3	26.4
Sample)	Natural gas	53.6	15.1	31.3
	Nuclear power	51.8	12.0	36.2
	Food preservatives	54.1	13.8	32.1
	Overall (N = 2328 trials)	53.2	13.6	33.2
	High benefit	58.6	12.0	29.4
	Low benefit	63.8	11.1	25.2
Study 2	High risk	67.6	8.0	24.5
(Prolific	Low risk	62.6	10.3	27.1
Sample)	Natural gas	64.6	12.4	23.1
	Nuclear power	59.7	8.1	32.2
	Food preservatives	65.1	10.6	24.4
	Overall (N = 2328 trials)	63.1	10.4	26.5

Note. A trial refers to one answer to a single scenario by a single participant. Given that there were three scenarios answered by 776 participants, in both studies, then the overall number of trials was 2328.

Subsequently, we also looked at the effect of the risk and benefit manipulation on the *non-manipulated* attribute (for details see Table S37). In the MTurk sample, of the 1238 trials in which the intended experimental manipulations worked, the effect on the non-manipulated attribute was congruent (as predicted), no change, and the opposite direction in 43.9%, 33.7%, and 22.5%, respectively. In the Prolific sample, of the 1469 trials in which the manipulations worked in the intended direction, the effect on the non-manipulated attribute was congruent, no change, and the opposite direction in 45.7%, 32.7%, 21.5%, of the cases respectively. These results echo those obtained in the original experiment where, of the trials in which the manipulated attribute was congruent, no change, and the intended direction, the effect on the non-manipulated attribute was congruent, no change, and the opposite direction in 45.7%, 32.7%, 21.5%, of the trials in which the manipulations worked in the intended direction, the effect on the non-manipulated attribute was congruent, no change, and the opposite direction in 45.7%, 32.7%, 21.5%, of the trials in which the manipulations worked in the intended direction, the effect on the non-manipulated attribute was congruent, no change, and the opposite direction in 45%, 31%, 23%, of the cases respectively.

Finally, we tested the correlation between risk and benefits. The AH model predicts that the non-manipulated attribute would change in a direction that is affectively congruent with the manipulation. For example, if the manipulation was designed to decrease perceived benefit, then perceived risk should increase, etc., leading to an inverse relationship between the manipulated and non-manipulated attributes. Following the original study, we decided to correlate the twelve t values produced as results of the analysis on the impact of the manipulated on the non-manipulated attribute. There were twelve t values as a result of the combination of the four affective information and three technology scenarios. The sign of the t values indicated whether a change occurred in the predicted direction (e.g., judged benefits of nuclear power ought to increase after reading information on low risk producing a positive t value). We found strong support for a negative correlation: MTurk sample: r(10) = -0.87, 95% CI [-0.96, -0.59], p = .003; Prolific sample: r(10) = -0.84, 95% CI [-0.95, -0.50], p < -0.50.001 (see Table S38. Note that the correlation in the original study was -.74. As predicted, the non-manipulated attribute changed in the inverse direction that is affectively congruent with the manipulation. The results confirm the predictions of the AH and replicate the findings obtained in Finucane et al. (2000)'s Study 2.

	Effect on the	Effect on the non-manipulated attribute				
Study	manipulated attribute	Percent of trials that manipulation worked	Percent of trials that effect was opposite manipulation	Percent of trials no change		
	Manipulation worked; N = 1238 (53.18 %)	43.9	22.5	33.7		
Study 1 (MTurk Sample)	No change; N = 773 (33.20 %)	25.5	17.9	56.7		
	Change was opposite; N =317 (13.62%)	30.3	36.0	33.8		
	Total; N = 2328	35.9	22.8	41.3		
Study 2 (Prolific Sample)	Manipulation worked; N = 1469 (63.1%)	45.7	21.5	32.7		
	No change; N = 618 (26.5%)	28.8	16.5	54.7		
	Change was opposite; N = 241 (10.4%)	29.9	33.6	36.5		
	Total; N = 2328	39.6	21.4	39.0		

Table S37. Effect of the risk and benefit manipulations on judgments of the non-manipulatedattribute.

Note. Trails refer to number of times the decision scenarios were answered— grouped under three different technology scenarios or experimental conditions; The table provides us with a summary of direction of changes in the non-manipulated attribute given the direction changes in the manipulated attributes.

Table S38

Comparison of the relationship between manipulated and non-manipulated attributes in the original study and our two replications.

Original study	Re	Replication summary

Table S44.	Comparing	Prolific sam	ple replication	and origina	l findings

Framework for evaluation of the replications

Table S45. Criteria for evaluation of replications by LeBel et al. (2018). A classification of relative methodological similarity of a replication study to an original study. "Same" ("different") indicates the design facet in question is the same (different) compared to an original study. IV = independent variable. DV = dependent variable. "Everything controllable" indicates design facets over which a researcher has control. Procedural details involve minor experimental particulars (e.g., task instruction wording, font, font size, etc.).

Target similarity	Highly similar				Highly dissimilar
Category	Direct replication				Conceptual replication
Design facet	Exact replication	Very close replication	Close replication	Far replication	Very far replication
Effect/ Hypothesis	Same/similar	Same/similar	Same/similar	Same/similar	Same/similar
IV operationalization	Same/similar	Same/similar	Same/similar	Different	Different
DV operationalization	Same/similar	Same/similar	Same/similar	Different	Different
IV stimuli	Same/similar	Same/similar	Different	Different	
DV stimuli	Same/similar	Same/similar	Different		
Procedural details	Same/similar	Different			
Physical setting	Same/similar	Different			
Contextual variables	Different				

Figure S6. Criteria for evaluation of replications by LeBel et al. (2019). A taxonomy for comparing replication effects to target article original findings.

A Signal Detected in Original Study
